ECITOXENIDIA BREVICORNIS SEEVERS, A RARE MYRMECOPHILOUS BEETLE, OCCURS IN VIRGINIA (COLEOPTERA: STAPHYLINIDAE: ALEOCHARINAE: LOMECHUSINI). — Staphylinid beetles are prominent among the various arthropods that have adapted to an often precarious life as commensals in ant colonies. Although this relationship seems to be more frequent in the tropics, several species of host ants do occur as far north and east in the United States so as to be represented in Virginia; army ants (Formicidae: Ecitoninae) such as Neivamyrmex in particular are frequently involved in this kind of myrmecophily. A summary of North American staphylinids known at that time to occur with Neivamyrmex was published some decades ago by C. H. Seevers (1959), in which the genera Microdontia (4 species), Ecitopora (1), Dinocoryna (5), Ecitonidia (1), and Ecitoxenidia (3) are accounted, most of the 14 species being recorded from North Carolina, Alabama, Kansas, and Arizona. A later review of the Aleocharinae (Seevers, 1978) dropped Ecitopora (as of dubious status) but did not otherwise alter the 1959 roster. A subsequent paper by Frank & Thomas (1981) provided a Florida locality for E. alabamae and a detailed habitus illustration of the species that shows its essential identity with E. brevicornis.

In the local context, North Carolina was credited by Seevers (1959) to have the species Dinocoryna bisinuata (Casey), D. schmitti (Wasmann), D. carolinensis Seevers, and Ecitoxenidia brevicornis Seevers. The last two species were based on specimens found in colonies of Neivamyrmex nigrescens (Cresson) at Southern Pines; apparently neither has been collected subsequently. Since this ant conducts virtually all of its activities underground, it is not often collected and its biology is poorly known.

On 2 August 2008, a blacklight operated at a small stream in Patrick County, Virginia, captured a single specimen of a small beetle of such curious form that identification even to family was initially retarded. On seeing this specimen at a later date, Dr. Arthur V. Evans recalled a similar image figured in the chapter on Staphylinidae in “American Beetles” (Newton et al., 2001: 318, fig. 278.22). By direct comparison of this beetle with the holotype of Ecitoxenidia brevicornis in the Field Museum of Natural History, Dr. A. F. Newton was able to establish conspecificity of the two individuals. This fortuitous collection is apparently only the second time that this species has been found (A. F. Newton, pers. comm.); its range is thus extended some
The several illustrations of this species in Seevers's (1959) description show the general appearance of the animal adequately, but, because they were made in a dorsal aspect, fail to represent the actual complexity of the forebody ornamentation. To aid in recognition of any future captures, I provide here some drawings made from oblique and lateral aspects (Figs. 1-2). Seevers correctly noted the presence of a median hyoid (“Y-shaped”) carina on the head and of two paramedian ridges on the pronotum, but these are more prominent than the dorsal view would suggest, and the supraocular carinae have not been previously mentioned.

In contrast, except for the greatly enlarged antennae with short, broad, discoid articles, the head and pronotum are essentially unmodified in the two species of Dinocoryna known from North Carolina. It is interesting to speculate on what selective factors – certainly including the host ants – have resulted in the structural innovations of E. brevicornis.

ACKNOWLEDGEMENTS

The assistance of Drs. Arthur V. Evans, A. F. Newton, and Deborah A. Waller in preparation of this note is gratefully acknowledged.
